Positron emission tomography (PET) has been in use for a few decades but its role in the management of brain tumours has only recently been recognized. The diagnostic accuracy of PET in brain tumours has been compared with that of conventional nuclear medicine imaging modalities such as computed tomography and magnetic resonance imaging (MRI) in the assessment of tumour size, location, histological grade and grade of malignancy. With respect to the assessment of tumour volume, MRI appears to be superior to PET. In the assessment of malignancy, the differences in the diagnostic accuracy of MRI and PET are not as striking. There is a close correlation between the diagnostic accuracy of MRI and PET. A combination of PET and MRI is recommended in the assessment of tumour grade. It appears that PET and MRI, each by itself, are not sensitive enough to replace surgical biopsy, especially in brain metastases. Although PET is now used more frequently in brain tumours, there are very few randomised studies comparing conventional nuclear medicine modalities with PET. Therefore, its routine use cannot be justified at present. Our Goal: Our goal is to help you enjoy a healthier you, and live longer. If you want to start eating healthier, then so do we.
